Abstract: - Load Forecasts are the primary factors which considered by electricity utility companies while planning power generation, power infrastructural development and load flows etc. Different forecasting techniques have been proposed from statistical to artificial intelligence-based models and the area of research is still growing. In our research work, considering the real time data of 33KV bus system which is having 34 buses and 54 lines. In this case, forecast the day ahead scheduling of various parameters such as load real power (Pload), voltage magnitude at each bus, apparent power flow between buses and total transmission losses for hourly basis and also forecasted the mentioned parameters for 5 days. The actual real time values are compared with forecasted values using two existing methods namely Extreme Learning Machine (ELM), moving average and proposed Moving Average-Extreme Learning Machine (MA-ELM) algorithm. In addition to this, forecasted the loads and losses for short term and long-term forecasting cases and verified through MATLAB programming.

Key-Words: - Short term load forecasting (STLF), Moving average (MA), Moving Average-Extreme Learning Machine (MA-ELM).

1 Introduction

categories, which are very short term, Short-term and Long-term forecasts. Particularly in power market these are very significant for the power system safety. To meet the high demand of urban electricity, exact and persistent short-term load forecasting in power systems operation and management plays an important role, especially in expansion of generating power, economic load scheduling and dispatch, and sustainability of electricity supply. For managing the power systems utilities [1] in planning, evaluations of market demand, load switching, reducing cost and finally guaranteed continuous electricity providing [2] short-term load forecasting (STLF) is considered as a key aspect.

Based on different parameters it can predict the future electrical load with the help of electricity load forecasting. The parameters can be atmospheric conditions, geographical conditions, economic conditions, time horizon such as hour, day and month etc. For the development of smart grid, predict loads in advance [3] for hourly, weekly or monthly by the use of Short-term electricity load forecasting (STLF). To deal with generation of energy and consumption, forecasting models' accuracy is very crucial. For the deregulated power system accurate forecasting model is a very important aspect. In the literature many works were

done based on forecasting of load. Neural networks, Time series forecasting technique and a Kalman filtering estimator are popularly used techniques for forecasting of load in smart grid applications [4-5].

Auto regressive moving average (ARMA) based models [6], Kalman filter [7], exponential smoothing (ES) [8], linear regression [9], and grey models (GMs) are called as Statistical models and are widely used in urban smart grid systems for short-term load forecasting. Auto regressive integrated moving average (ARIMA) models are also used to manage the time series analysis in Smart grid for short term load forecasting[12].

Based on artificial intelligence/machine learning (ML) or conventional methods Load forecasting can be performed. Based on support vector machines, fuzzy logic, and artificial neural networks (ANNs) [10] methods can give better performance than the conventional methods. Deep learning for STLF [11] can be used for further extensions. Because of good performance and simple implementation ANN based forecasting method can be preferred among the ML forecast models.

The objective of the paper is to enrich the accuracy of forecasting by extreme learning machine algorithm. In this paper, MA-ELM is a novel hybrid algorithm has been proposed for forecasting of load real power, voltage magnitude and transmission line losses. It has a combinational feature of both

Moving Average and Extreme Learning Machine (MA-ELM) algorithm. In the present paper, it has proposed very short term, short term and long-term forecasting and estimate various parameters such as load real power (P_{load}), voltage magnitude at each bus, apparent power flow between buses and total transmission losses. From the obtained results, observed that the MA-ELM algorithm offers good performance in the point of error metrics and convergence time rather than Moving Average and ELM algorithms. In real time, this technique is very much helpful for forecasting of load[13]. The forecasting results are obtained through MATLAB 2016a software.

Paper is organized that Section I gives the electric load forecasting introduction. Section II presents the mathematical modelling of extreme learning machine algorithm and moving average approach. section III describes the proposed methodology and the proposed model performance through MATLAB programming is discussed in Section IV.

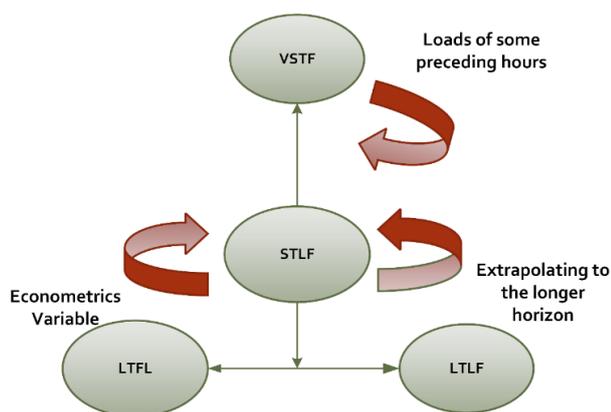

Fig. 1: Process flow of conversion between STLF and LTFL.

STLF is the most popular approach among the various options. Because of its inherent connectedness to other types of projections, it plays a crucial role in the creation of economic and secure operating strategies for the power system. By adding econometric variables to the STLF and projecting the model to a longer horizon, the STLF can be turned into MTLF and LTFL. The VSTLF model, on the other hand, can be created from STLF by include the loads from the previous hours as part of the STLF model's inputs. Short-term load forecasting can incorporate the autocorrelation of the current hour load and the preceding hour load. Additionally, the residuals of previous load can be gathered and used to create a new series based on the STLF. By projecting future residuals and adding them back to the short-term prediction, a very short-term forecast can be obtained. Figure 1 depicts the

conversion process between STLF and LTLF, MTLF and VSTLF.

2 Methodology

2.1 Extreme Learning Machine Algorithm

The Extreme Learning Machine model is a Single Layer Feed-forward Network (SLFN) contains input, hidden and output layers. Input layer nodes are interconnected with the hidden layer nodes. This interconnection is known as input layer weights. The hidden layer is the layer between the input and output layers. Each hidden layer nodes are also interconnected with all the output layer nodes. This interconnection is known as the output layer weights. Using different training algorithm weights can be adjusted. The output nodes has been represented the horizon of forecast.

The Extreme Learning Machine (ELM) is a new training algorithm and to reach global minima, it does not require iterative tuning. When compares to gradient descent-based training algorithm, this algorithm has to reduce the training time. The ELM training speed is very faster while comparing with gradient-descent based training algorithm. It can avoid to choose additional parameters like learning rate and stopping criterion. The empirical evidence shows that it has universal approximation capabilities and good generalization.

In ELM, randomly chosen the input weights and hidden biases (linking the input layer with the hidden layer), and by using Moore-Penrose inverse the output weights are determined analytically (linking the hidden layer with the output layer). With a smaller number of iterations, the convergence of ELM is much faster. The ELM can be modelled mathematically as follows:

Given training set Input and Actual Output samples, $(x_i, y_i); i=1, 2, \dots, S, x_i \in R^p, y_i \in R^q$, where x and y are the input and target matrices of dimensions p and q .

With N hidden layer neurons, the SLFN neural Network is written as

$$\sum_{i=1}^N \beta_i G_i(x_j) = \sum_{i=1}^N \beta_i G(w_i \cdot x_j + b_i) = o_j \quad (1)$$

where w_i is the hidden layer input weight matrix, β_i is the hidden layer output weight matrix, b_i is the threshold of the hidden layer, and $G(x)$ is the activation function. To minimize training error by ELM search:

$$\sum_{i=1}^N \beta_i G(w_i \cdot x_j + b_i) = y_j \quad (2)$$

The above equations can be re-written as:

$$H\beta = Y \quad (3)$$

H is the hidden layer output matrix;

The output weight matrix can be calculated by:

$$\beta = H^+Y \quad (4)$$

Where H^+ is the Moore–Penrose inverse of H.

2.1.1 Moving Average Approach

In this method, Moving Average formula has been used to average the mentioned number of periods to calculate the next forecasted parameter.

3 Proposed MA-ELM Algorithm

For forecasting of future demand of Chittoor District, APSPDCL, Andhra Pradesh in India, the proposed MA-ELM algorithm is applied. Moving Average-Extreme Learning Machine algorithm:

MA-ELM is a hybrid approach gives combined features of both Moving average and Extreme Learning Machine algorithm. Simple Moving Average approach for prediction and capability of ELM improves overall efficiency and reduces simulation time with least training. Moving average method is purely statistical method, here we have to possibility to apply error analysis and stability analysis cannot be applied. The mathematical formulation of MA-ELM can be explained as follows:

Let the training set Input and Actual Output sample patterns be $(a_i, b_i); i=1,2,\dots,S,S+1$. Where $a_i=[a_{i1}, a_{i2}, a_{i3}, \dots, a_{is}, a_{i(s+1)}]^T$ represents input parameters and $b_i=[b_{i1}, b_{i2}, \dots, b_{is}]^T$ represents output parameters.

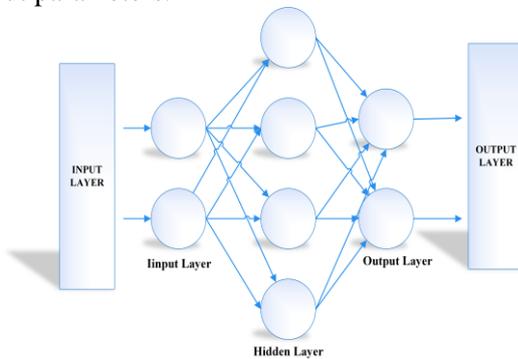

Fig. 2: Single hidden layer MA-ELM structure

Where b_{i1} =average of a_{i1} and a_{i2} , b_{i2} =average of a_{i2} and a_{i3} . Similarly, b_{is} =average of a_{is} and $a_{i(s+1)}$. Mathematical function establishes MA-ELM with

activation function $\phi(\cdot)$ and L number of hidden nodes, it can be expressed as

$$G(a_j) = \sum_{i=1}^N \eta_i \phi(\lambda_i a_j + \mu_i); j=1,2,\dots,(s+1) \quad (5)$$

The above expression written in matrix notation as $\phi\eta=A^{\oplus}$ (6)

The activation function is $\phi(\cdot)$ in matrix form is

$$\phi = \begin{bmatrix} \phi(\lambda_1 a_1 + \mu_1) & \phi(\lambda_2 a_1 + \mu_2) & \dots & \phi(\lambda_L a_1 + \mu_L) \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ \phi(\lambda_1 a_{s+1} + \mu_1) & \cdot & \dots & \phi(\lambda_L a_{s+1} + \mu_L) \end{bmatrix}$$

A^{\oplus} is the target matrix,

$$A^{\oplus} = [b_1, b_2, \dots, b_s]^T \quad (7)$$

The parameters λ and μ has been randomly chosen and cost function is minimised based on back propagation learning algorithm. The output weight matrix $\tilde{\eta}$ can be obtained with the help of singular value decomposition (SVD) method using Moore–Penrose inverse approach. It can be calculated as:

$$\tilde{\eta} = \phi^{-1} A^{\oplus} \quad (8)$$

In the present work, forecasting of various parameters has been done for Chittoor District, APSPDCL area of the state of Andhra Pradesh, India.

Step 1: Collected the bus data, line data and previous load data for past ten years belongs to Chittoor district from APSPDCL Head Office, Tirupati.

Step 2: Using MA-ELM algorithm forecasting has been done for selected parameters in the given area.

4 Results and Analysis

In the present work, considered very short-term load forecasting and estimate the day ahead scheduling of various parameters such as load real power (P_{load}), voltage magnitude at each bus, apparent power flow between buses and total transmission losses for hourly basis and also forecasted the mentioned parameters for 5 days.

In “Table 1” shown the actual load values, forecasted loads using ELM, MA method and proposed MA-ELM method values of load real power (P_{load}) for 34 buses. From the tabulated results, concludes that the proposed method gives better performance when comparing with the two existing methods. The results of load real power with proposed method is shown in “Figure 3”.

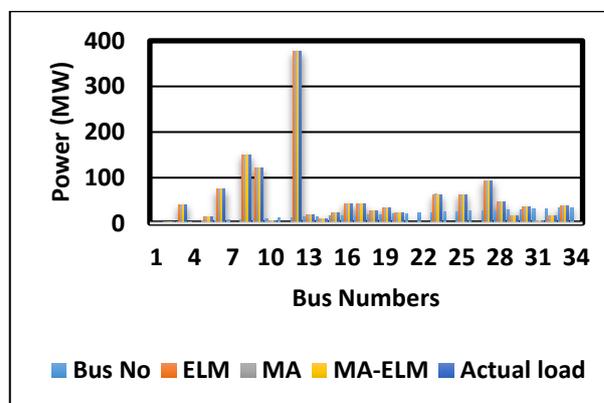

Fig. 3: Load real Power P_{load}

In table.2, shown the actual voltage magnitude values, forecasted values with ELM, MA methods and proposed MA-ELM method for 34 buses. The graphical representation of voltage magnitudes at buses with proposed and existing methods is shown in “Fig. 4”. From this, it has observed that by the proposed method the voltage magnitude is slightly increased

In “Table 3” mentioned the actual values of apparent power flows (S_{flow}) between buses (for 54 lines), forecasted power flows using existing methods and proposed method values of line flows. The results of apparent power flows with proposed method is shown in “Fig 5”. From the output values understand that the magnitudes of power flows are optimally scheduled with proposed method.

In “Table 4” shown the actual total power losses and forecasted losses occurred with existing methods and proposed method. The graphical representation of total power losses with proposed method and existing methods are shown in “Fig. 6”. From the obtained data the total power losses are minimized with the proposed method when compares with the existing methods.

In “Table 5” tabulated the actual total power losses and occurrence of forecasted losses with existing methods and proposed method for hour wise upto 24 hours on 01-01-2020. “Figure 8” shows the graphical representation of the power losses on 01-01-2020. Hence, it has observed that the losses are minimized with the efficiency of proposed method.

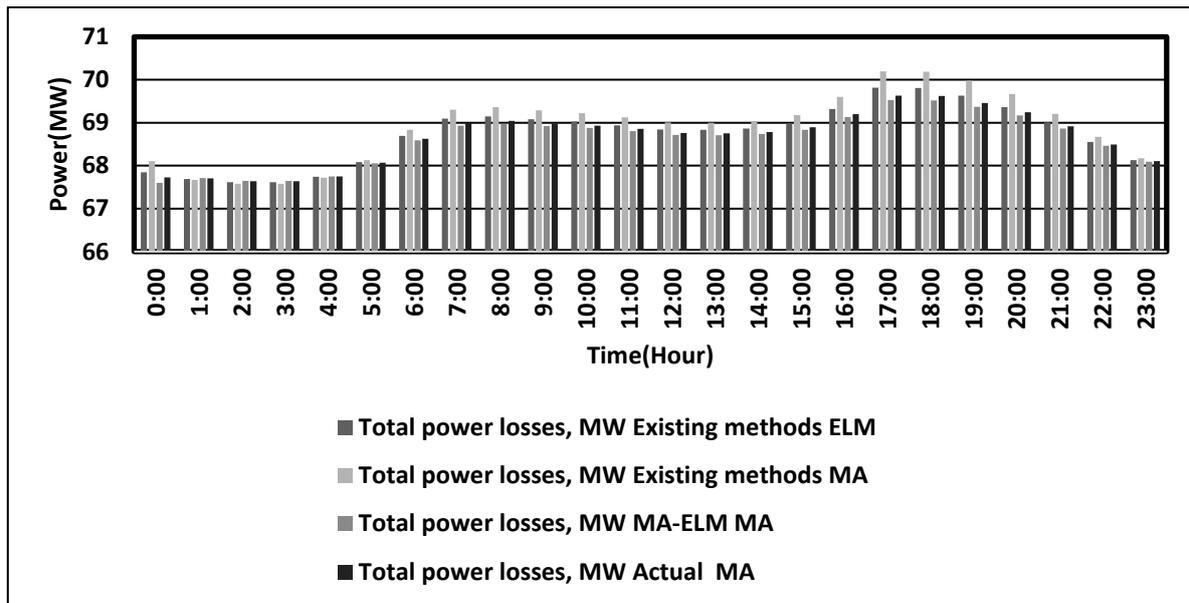

Fig. 7: Total Power losses on 01-01-2020

“Table 6” shows that the comparison of total power losses for actual load and total power losses for the forecasted load using proposed MA-ELM method. “Figure 7” gives the results with comparison of total power losses for actual load and total power losses for the forecasted load with proposed method. From the output results concludes that the losses are reduced with the proposed method when compares with the mentioned two existing methods. In “Table 7” considers the average of daily loads (month) and tabulated total real power load (Pload) and total power losses for monthly basis and upto 1 year with

proposed method of forecasting and “Figure 8” shows its graphical representation. “Table 8” shows long term forecasting case, it has considered the annual total load real power (Pload) and total power losses up to 10 years with proposed method of forecasting. So, in “Table 8” tabulated the total real power load and total power losses for yearly basis upto 10 years. “Figure 10” shows the graphical representation of the results shown in Table 8.

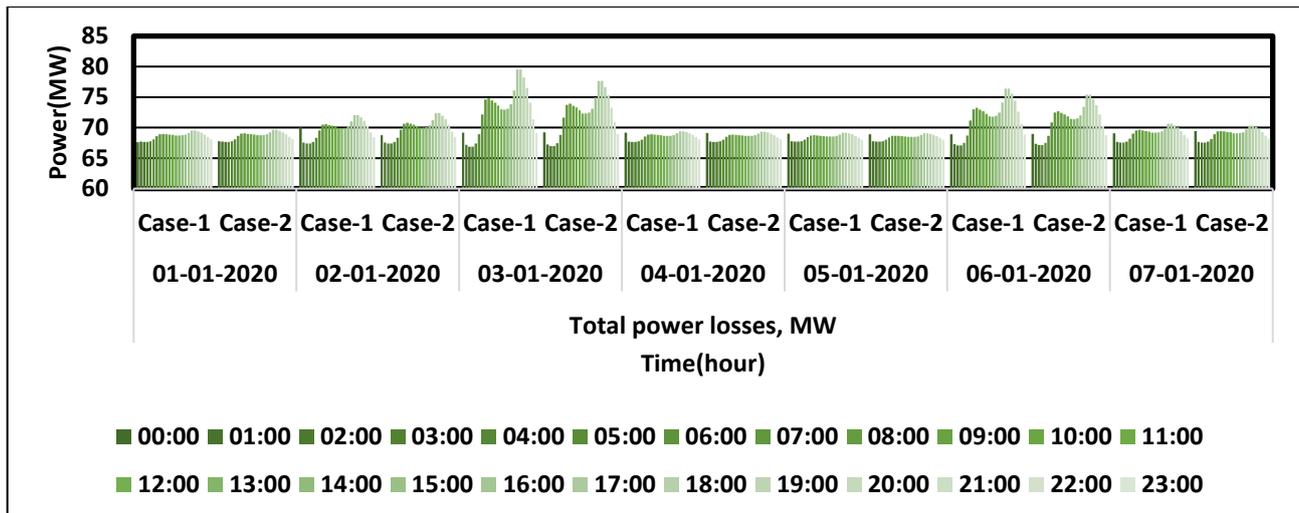

Fig. 8: Total power losses for the forecasted load. case-1: Using proposed MA-ELM method, case-2: Actual load (real time data)

Table 6. Case-1: Total power losses for the forecasted load using proposed Moving Average-ELM method. Case-2: Total power losses for the actual load (real time data).

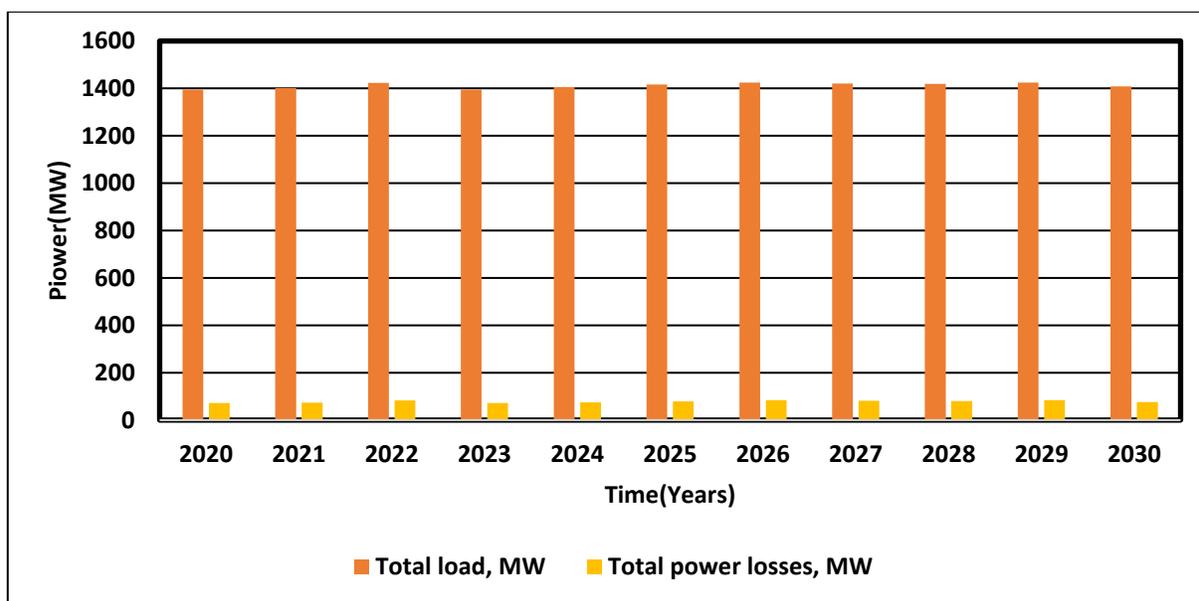

Fig. 10: Long Term Forecasting

5 Conclusions

In this paper, presented the forecasted load values at buses, voltage magnitudes at buses, apparent power flows and total power losses for the real time data of 33KV bus system has been presented by using Moving Average Extreme Learning method. Also presented the short term and long term forecasted values of loads and total power losses. The obtained results are compared with ELM and moving average methods and results are validated through MATLAB.
